ARRAY

Arrays

Characteristics

- Memory layout: hold values in a contiguous block of memory.
- **Fixed Size**: the size of an array is defined when it is created and cannot be changed. However, high-level languages have different implementations, making it dynamic.
- Homogeneous elements: all elements are of the same data type (int, float, char...)
- **Efficiency**: accessing elements by index is very efficient *O*(1), since each index maps directly to a memory location. Also, range scans benefit from CPU cache lines since arrays are stored in contiguous blocks of memory.

Arrays – Kadane's algorithm

Problem Statement

- Given an array of numbers and a target, example: array [2,7,11,15] and target 9
- Return indices of two numbers where they add up to target
- **Output**: [0,1]

$$array[0] + array[1] = 2 + 7 = 9$$

Solution

- Iterative over each number in the array
- Calculate the difference between target and each number, example:

```
array[0] = 2, target 9, then 9 - 2 = 7
```

- Now we know we need the number 7 to sum up to 9
- Check in a hashmap if we have 7 in some part of the array

```
hash[7] exists?
```

- If yes, return the current index and the index of 7
- If not, store the index of the current number in the hashmap for future evaluation

$$hash[2] = 0$$

Code - Two Sum

LeetCode leetcode.com/problems/two-sum

Code O(n)

```
vector<int> twoSum(vector<int>& nums, int target) {
    std::unordered map<int, int> numMap;
   // O(n)
   // n being the size of nums
   for (int i = 0; i < nums.size(); i++) {</pre>
        // current number of the array
       int number = nums[i];
        int diff = target - number;
        // check if the difference is in some part of the array
       // by using a hashmap
        if (numMap.find(diff) != numMap.end()) {
            return { numMap[diff], i};
        // register the current number index
        numMap[number] = i;
   // no matches
   return {};
```

Problem - Best Time to Buy and Sell Stock

https://leetcode.com/problems/best-time-to-buy-and-sell-stock

You are given an array prices where prices[i] is the price of a given stock on the i^{th} day.

You want to maximize your profit by choosing a single day to buy one stock and choosing a different day in the future to sell that stock.

Return the maximum profit you can achieve from this transaction. If you cannot achieve any profit, return 0.

Example 1

Input: prices = [7,1,5,3,6,4]

Output: 5

Explanation: Buy on day 2 (price = 1) and sell on day 5 (price = 6), profit = 6-1 = 5.

Note that buying on day 2 and selling on day 1 is not allowed because you must buy before you sell.

Example 2

Input: prices = [7,6,4,3,1]

Output: 0

Explanation: In this case, no transactions are done and the max profit = 0.

Solution - Best Time to Buy and Sell Stock

https://leetcode.com/problems/best-time-to-buy-and-sell-stock

```
int maxProfit(vector<int>& prices) {
   int profit = 0;
   int buy = prices[0];
   for (auto i = 1; i < prices.size(); i++) {
      if (prices[i] < buy) {
        buy = prices[i];
      } else if (prices[i] - buy > profit) {
           profit = prices[i] - buy;
      }
   }
   return profit;
}
```
