INTERVAL

Some Common Patterns

Merge Intervals

- Sort by start time
- Merge if current.start <= previous.end</p>
- Classic use: merging calendar events, range compression

Interval Scheduling (Max Non-overlapping Intervals)

- Sort by end time
- Greedy: select interval only if start >= last_selected.end
- Optimal because ending earlier leaves more time for future

Minimum Number of Arrows to Burst Balloons

- Same as interval scheduling
- Sort by end time
- Count how many non-overlapping intervals = minimum arrows needed

Some Common Patterns II

Minimum Meeting Rooms

- Sort by start and end times separately
- Use a min-heap to track active meetings
- Greedy, but uses more advanced data structure

Can Attend All Meetings?

- Sort by start time
- Check if any overlap with previous: if start < previous.end, return false

Problem - 57. Insert Interval

leetcode.com/problems/insert-interval

Problem Statement

- You are given an array of intervals, where intervals[i] = [start, endi] and newInterval = [start, end]
- newInterval must be inserted into intervals
- Overlapping intervals must be merged
- Example

intervals = [[1,2],[3,5],[6,7],[8,10],[12,16]] newInterval = [4,8]

Output: [[1,2],[3,10],[12,16]]

Solution - 57. Insert Interval

leetcode.com/problems/insert-interval

Solution

- Sort intervals by the first element (start)
- Initialize result
- Solve in three loops:
 - 1. While there is no overlap with **newInterval**, add to **intervals[i]** to **result**
 - 2. While it overlaps, merge **newInterval**
 - 3. While until the end intervals and add the remaining intervals[i]

leetcode.com/problems/insert-interval

Code

Time: **O(n)** Space: **O(n)** where n is the size of intervals

```
vector<vector<int>> insert(vector<vector<int>>& intervals, vector<int>& newInterval) {
    vector<vector<int>> result;
    int tupleIndex = 0;
    int totalTuples = intervals.size();
    // 1. check if it overlaps
    // 1 ----- 2
    while (tupleIndex < totalTuples && intervals[tupleIndex][1] < newInterval[0]) {</pre>
        result.push_back(intervals[tupleIndex]);
        ++tupleIndex;
    // 2. merge overlap. We already know there is an overlap here,
    // otherwise it should be sorted out in the previous step
    // 3 ---- 5
          4 ---- 8
    while (tupleIndex < totalTuples && intervals[tupleIndex][0] <= newInterval[1]) {</pre>
        newInterval[0] = min(newInterval[0], intervals[tupleIndex][0]);
        newInterval[1] = max(newInterval[1], intervals[tupleIndex][1]);
        ++tupleIndex;
    result.push back(newInterval);
    // 3. add remaining parts
    while (tupleIndex < totalTuples) {</pre>
        result.push back(intervals[tupleIndex]);
        ++tupleIndex;
    return result;
```

leetcode.com/problems/merge-intervals

Problem Statement

You are given an array of intervals, example:

```
intervals = [[1,3],[2,6],[8,10],[15,18]]
```

Merge all overlapping intervals. So the output should be:

```
[[1,6],[8,10],[15,18]]
```

Interval [1,3] was merged with [2,6]

```
LeetCode
```

leetcode.com/problems/merge-intervals

Solution

- Sort the array based on the beginning of the interval
- In C++, when applying sort(intervals.begin(), intervals.end())
 the default comparator compares vector<vector<int>> lexicographically:
 - it first compares the first element [0] of each sub-vector
 - if those are equal, it compares the second element [1] and so on
- Go over each interval and compare
- interval[i][begin] <= interval[i 1][end] ?then merge</pre>
- To merge, set the current interval[i][begin] to interval[i -1][begin] and set the
 interval[i][end] to the maximum value between interval[i][end] and interval[i -1][end]
- If no merge is necessary, push the previous interval to the result array
- Once the loop finishes, add the last element and return the result

Code - 56. Merge Intervals

```
E LeetCode
```

leetcode.com/problems/merge-intervals

Code Time: O(n log n) Space: O(n)

```
vector<vector<int>> merge(vector<vector<int>>& intervals) {
   if (intervals.empty()) return {};
    sort(intervals.begin(), intervals.end());
   vector<vector<int>> result;
   result.push back(intervals[0]);
   for (int i = 1; i < intervals.size(); ++i) {</pre>
        vector<int>& current = intervals[i];
        vector<int>& previous = result.back();
       // check if they overlap, if so merge...
       // they're sorted, we know that:
       // previous[0] >= current[0]
       // 1 --- 3 (previous)
       // 2 ---- 6 (current)
       if (current[0] <= previous[1]) {</pre>
           // merge
            previous[1] = max(previous[1], current[1]);
       } else {
            result.push back(current);
   return result;
```

leetcode.com/problems/non-overlapping-intervals

Problem Statement

- You are given an array of intervals vector<vector<int>> with start and end, Example:
 - intervals = [[1,2],[2,3],[3,4],[1,3]]
- The intervals must not overlap each over
- You have to remove the minimum number of pairs to make it non-overlapping

Solution – 435. Non-overlapping Intervals

leetcode.com/problems/non-overlapping-intervals

Solution

Sort the array by the ending time:

```
[[1,2],[2,3],[3,4],[1,3]] \rightarrow [[1,2],[2,3],[1,3],[3,4]]
```

In C++ a lambda function can be used with sort:

```
sort(intervals.begin(), intervals.end(), [](const vector<int>& a, const vector<int>&b) {
   return a[1] < b[1];
});</pre>
```

- Note that std::sort is not stable (opposite of std::stable_sort), so there is no guarantees that [2,3] comes before [1,3]. But for this algorithm, it doesn't matter
- Iterate over the array and check overlaps by comparing the end[i] with begin[i 1]
- If they overlap, logically remove the current pair and count + 1
- Logically removing means just setting the end to compare to the previous element, so "skip" the current interval

Code – 435. Non-overlapping Intervals

```
LeetCode
```

leetcode.com/problems/non-overlapping-intervals

```
Code Time: O(n log n) Space: O(1)
```

```
int eraseOverlapIntervals(vector<vector<int>>& intervals) {
    // sort by the ending time O(log n)
    sort(intervals.begin(), intervals.end(), [](const auto& a, const auto& b) {
            return a[1] < b[1];
    });
    int result= 0;
    int end = intervals[0][1];
    // O(n)
    for (int i = 1; i < intervals.size(); ++i) {</pre>
        // does it overlaps?
        if (intervals[i][0] < end) {</pre>
            ++result;
        } else {
            // it doesn't overlap, just 'skip'
            // the current interval
            end = intervals[i][1];
    return result;
```

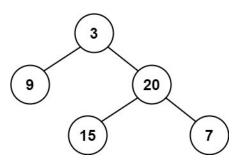

leetcode.com/problems/balanced-binary-tree

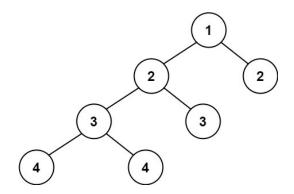

Problem

- You are given the root of a binary tree
- Return true if it is height-balanced
- A tree is height-balanced when the height of two subtrees does not differ by two

Height balanced

Not Height balanced

leetcode.com/problems/balanced-binary-tree

Solution

- Recursive approach: go all the way down
- Calculate the height of the left subtree
- Calculate the height of the right subtree
- Compare both to check if they differ by more than one
- Continue going up the tree to check all the nodes

Problem - 110. Balanced Binary Tree

LeetCode

leetcode.com/problems/balanced-binary-tree

Code Time: O(n) Space: O(h) where n is the number of the nodes and h is the height of the tree

```
int checkHeight(TreeNode* node) {
    if (!node) return 0;
    int left = checkHeight(node->left);
   // left tree is unbalanced
    if (left == -1) return -1;
    int right = checkHeight(node->right);
   // right tree is unbalanced
   if (right == -1) return -1;
   // check the different, -1 is unbalanced
    if (abs(left - right) > 1) return -1;
    return max(left, right) + 1;
bool isBalanced(TreeNode* root) {
    return checkHeight(root) != -1;
```
